

Stack and Queue Quick Revision

Data Structures | Unit 2: Stacks and Queues

Stacks and queues are linear structures that restrict where elements are added and removed.

- Stack is LIFO (last in, first out). Operations: push, pop, peek, isEmpty.
- Typical uses of a stack: function calls, undo, balanced-bracket checking, expression evaluation.
- Queue is FIFO (first in, first out). Operations: enqueue, dequeue, front, isEmpty.
- Variants: circular queue, double-ended queue (deque), priority queue.
- Stack overflow happens when pushing to a full stack; underflow when popping an empty one.
